

Each panel: per-gene distribution on one richness axis. Dark dots = real values from the 20 published deep dives. Violin shape + IQR box = synthesised 5,000-draw fan extrapolating to a full cohort (lognormal for papers_found around the methods-documented median 234.5 / range 50–400; Gaussian around the empirical mean $\pm$ std (or 15%% mean, whichever larger) for the other axes). MOCK pending the discover-only backfill for papers_found and the full cohort sweep.
