e

Dark dots = real values from the 20 published deep dives (6 surface_accessibility='no'; 14 surface=yes-even-weak). Panels a/b split by verdict bucket; panels c/d/e restricted to surface=yes since non-surface proteins lack extracellular evidence by definition. Violin shape + IQR box = synthesised 5,000-draw fan extrapolating to a full cohort (lognormal for papers_found around the methods-documented median 234.5 / range 50–400, offset down for the 'no' bucket; Gaussian around the per-bucket empirical mean $\pm$ std (or 15%% mean, whichever larger) for the other axes).
MOCK pending the discover-only backfill for papers_found and the full cohort sweep.
